Logistic regression

> It is a supervised classification model

Independent / dependent

helps to predict dependent
To be predicted

- In linear regression data is continuous
- but in the logistic the data to be predicted is categorical, binary (discrete) (0, 1) (yes, no)

A student studies 5 hours and predict he will pass or not on basis of given data of study hours and Exam result as 0, 1 (find probability)

Sigmoid function is used

$$Y = \frac{1}{1 + e^{-(a_0 + a_1 x)}}$$

↓
Predicting variable

(0, 1)

only between 0 and 1 high or low

Maximum likely hood function Estimation

↳ Cost function is optimized again and Gradient descent again.

If x is 0 where y will intercept

a_0 = Intercept

a_1 = Coefficient

If x is incremented by 1 how much y will change.

Maximum likely hood method is used to calculate a_0 and a_1 .

In which COS function is further optimized by Gradient decent method

For now we assume $x = 5$ - hours of study

$$a_0 = -1.5 \quad a_1 = 0.6$$

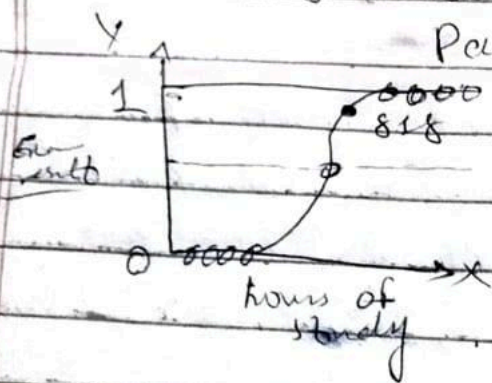

$$y = \frac{1}{1 + e^{-(a_0 + a_1 x)}}$$

$$a_0 + a_1 x = (-1.5 + 0.6 \times 5)$$

$$\Rightarrow y = \frac{1}{1 + e^{-1.5}} = 1.5$$

$\approx .818 \rightarrow$ 81 percent chance he will

Pass if he studies 5 hours

Linear regression

- > Continuous
- > Price hike based on house or land area

Logistic regression

- > Categorized (Yes or No)
- > On base of study hours student will pass or not
Yes or No
(Classified)
